Problem 1: Logistic difference equation

In a discrete time model for population growth, the value x (number of cells divided by the maximum number supported by the habitat) at time $t + 1$ is calculated from the value at time t according to the difference equation

$$x_{t+1} = rx_t(1 - x_t).$$

- (a) Determine the equilibrium points x^* of the system. (1 point)
- (b) Are the points stable for $r = 0.5$, $r = 1.5$, $r = 2.5$? (1 point)
- (c) Confirm this by numerically iterating the difference equation. (1 point)
- (d) Examine the stability and behaviour for $r = 3.5$. (1 point)
Hint: Plot the Poincaré section of x_t against x_{t-1} , and remove transient points.
- (e) What happens for $r = 3.9$? (1 point)

Problem 2: Logistic growth in continuous time

The logistic model for population growth is:

$$\frac{dx(t)}{dt} = \lambda x(t) \left(1 - \frac{x(t)}{K}\right) \quad (1)$$

- (a) Show, by direct integration of (1), that the solution is given by: (2 points)

$$x(t) = \frac{Kx_0e^{\lambda t}}{K + x_0(e^{\lambda t} - 1)}.$$

Hint: Use separation of variables and partial fractions.

- (b) Find the equilibrium points of the system and discuss their stability. (1 point)
- (c) Numerically integrate to demonstrate the results above. (2 points)
